Eco Action Note

CODE2THINK Challenge 10 - ECOGUARD

Data note

The concern below uses clearly labelled simulated EcoGuard classroom readings. It does not claim to be an actual campus measurement.

Issue observed

The simulated seven-day readings for the Cafeteria show occasional AQI values above 150 around busy meal times. Vehicle idling near the entrance is a controllable source of pollution exposure for students waiting outside.

Action proposed

Run a seven-day **No-Idling Week** at the Cafeteria entrance. Place a visible sign asking drivers to switch off engines while waiting. Student volunteers will remind drivers during lunch hours, and facilities staff will keep the pickup area clear so vehicles do not queue unnecessarily.

Measurable target for the next seven days

Record AQI at the Cafeteria in the same lunch-time window every day and count idling vehicles for ten minutes. The target is to reduce observed idling vehicles by **50%** from the first-day baseline and have **no more than one AQI reading above 150** during the week.

How impact will be checked

EcoGuard will store the daily AQI readings and display risk days. A paper tally will record idling vehicles. At week end, compare the day-one vehicle count and AQI with the seven-day result. If the target is missed, move the sign closer to the entrance and repeat the awareness reminder the following week.
